Laboratory Activity 2: Populating Pages

Part 1.

The LandingPageController class extends the Controller class and defines a single method *index()*.

The *index()* method generates an array of 12 books with unique IDs, titles, images, ratings, and descriptions. Each book's data is stored in an associative array and added to the \$featuredBooks array.

Finally, the method returns a view called 'LandingPage' and passes the \$featuredBooks array as a variable to the view.

```
Route::get('/', [LandingPageController::class, 'index'])->name('landing');
```

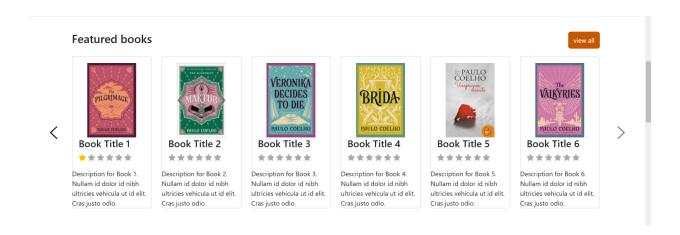

The landing page route is a simple route that displays the landing page view.

The route is named 'landing' so that it can be easily referenced in code.

The route is handled by the index method of the LandingPageController class.

Part 2:

This method inside the controller dynamically generates a list of **featured books** and passes it to the LandingPage view. Below is the content created by the controller.

```
FinalPro > public > assets > bootstrap > js > 18 star-ratingjs > ② document.addfventtistener("DOMContentLoaded") callback > ② ratingContainers.forEach() callback > ② stars.forFach() cal
```

This JavaScript code adds interactivity to a **star rating system** for books. When the user clicks the star, an alert message appears.

After clicking OK, it updates the visual appearance of the stars.
